Foreword

This talk is based on

- FG,S.Lottini, M.Panero, A.Rago, Random percolation as a gauge theory, Nucl.Phys.B 179 (2005) 255 [arXiv:cond-mat/0502339].
- S.Lottini,FG, *The glue-ball spectrum of random percolation* PoS LAT2005:292 [arXiv:hep-lat/0510034]
- FG, Where is the confining string in random percolation [arXiv:hep-lat/0601011]
- plus work in progress with Stefano Lottini and Pietro Giudice

Plan of the talk

1 Motivation

2 Percolation as a gauge theory

- Confinement and scaling
- Deconfinement at finite T
- "Magnetic" monopole condensation

3 Roughening

- The two confining phases
- Quantum string fluctuations
- A strong coupling expansion

4 Conclusions

Motivation

F. Gliozzi (DFT & INFN, Universitá di Torino

Roughening in percolation

SM&FT 2006 4/44

Motivation

- The main features of the confining phase of whatever gauge theory do not depend very much on the nature of the gauge group G
 - ⇒ Area decay of large Wilson loops $\langle W(R, T) \rangle \propto e^{-\sigma RT}$
 - Universal, G independent, 1/R and 1/R³ corrections of the confining potential

 $V(R) = -\lim_{T \to \infty} \frac{\log W(R,T)}{T} \simeq \sigma R - \frac{\pi (D-2)}{24R} - \frac{\pi^2 (D-2)^2}{1152 \sigma R^3}$

glue-ball spectrum:

$$egin{array}{l} rac{m_{0^+}}{\sqrt{\sigma}} = 3.87(3) \; SU(2) \;, \; D = 3 + 1 \ rac{m_{0^+}}{\sqrt{\sigma}} = 3.65(3) \; SU(3) \;, \; D = 3 + 1 \ rac{m_{0^+}}{\sqrt{\sigma}} = 3.08(3) \; Z_2 \quad , D = 2 + 1 \end{array}$$

⇒ Deconfining temperature $T_c/\sqrt{\sigma} = 0.596(4) + 0.453(30)/N^2$, SU(N), D = 3 + 1.

Motivation

- Also the proposed confinement mechanisms (*magnetic monopole condensation , center vortices, confining string,...*) do not depend crucially on the gauge group
- There is a good numerical support of these mechanisms but there is no proof
- The various mechanisms are mutually inter-related, but the logical implications are not completely clear
- Search for a drastically simplified version of a confining gauge theory in which
 - ✤ The area decay of the Wilson loops is true by construction
 - The gauge group is trivial
 - Check whether the other general properties of the confining phase follow

Random Percolation

- ★ Percolation studies random graphs in a lattice. generated by switching on each link (or site) with probability p
- * Near the percolation threshold $p = p_c$ the connected components (clusters) of these random graphs show universal features
- The theoretical description of the percolation processes is conventionally given in terms of the cluster sizes and most of the universal scalings deal with size distribution of clusters
- The point of view which is taken here is different: We focus on topological entanglement of random clusters and use it to describe how percolation theory can be considered as a paradigm of confining gauge theory.

< □ > < □ > < □ > < □ >

Observables

- $\star\,$ The most basic observables of any gauge theory are the Wilson loops ${\it W}_{\gamma}({\it C})$
- ★ Two inputs:
 - a closed path γ
 - A gauge configuration C
- ⋆ one output :
 - A real or complex number $W_{\gamma}(C)$

 $m{C}
ightarrow m{W}_{\gamma}(m{C})$

The setup

Define the following purely geometric setting

- **1** Generate a sample of random graphs $\{G_1, G_2, ...\}$ simply by populating each of the links (or sites) of a (cubic) lattice *independently* with occupation probability *p*.
- 2 The physical observables of this system, that we call still Wilson operators W_{γ} , are associated to arbitrary loops γ of the dual lattice and obey the following rule
 - $\Rightarrow W_{\gamma}(G_i) = 1$ if no cluster of the configuration G_i is topologically linked to γ ;
 - \Rightarrow $W_{\gamma}(G_i) = 0$ otherwise;
 - $\Leftrightarrow \langle W_{\gamma} \rangle = \lim_{n \to \infty} \sum_{i=1}^{n} W_{\gamma}(G_i)/n.$

Topological linking of W

F. Gliozzi (DFT & INFN, Universitá di Torino

SM&FT 2006 11 /

2

イロト イヨト イヨト イヨト

linking of W depends only on closed paths

F. Gliozzi (DFT & INFN, Universitá di Torino)

linking of W depends only on closed paths

- Adding or removing bridges does not change the value of W
- The invariance of W under this local transformation is similar to a gauge transformation

< < >>

- * When $p < p_c$ only finite clusters form
- If the linear size of γ is much larger than the typical size of the clusters W_γ obeys a *perimeter law*
- Implicit when p ≥ p_c an infinite, percolating cluster form
 ⇒ large Wilson loops
 obey an *area law*

Confinement and scaling

F. Gliozzi (DFT & INFN, Universit<u>á di Torino</u>

-

• • • • • • • • • • • • •

Area law for square Wilson loops

Scaling and Universality of σ

The expected behaviour of σ in the scaling region is

 $\sigma(\boldsymbol{\rho}) = S (\boldsymbol{\rho} - \boldsymbol{\rho}_c)^{2\nu}$

with

.

 $\nu = 0.8765(16)(2)$

Lattice	p_c	S	$\chi^2/d.o.f$
SC site	0.3116081(7)(2)	3.370(8)	1.15
SC bond	0.2488126(5)	8.90(3)	0.30
BCC bond	0.1802875(10)	22.07(2)	0.98

Deconfinement at finite T

F. Gliozzi (DFT & INFN, Universitá di Torino

Deconfinement at finite T

- The percolation process explains also deconfinement at finite temperature as a *dimensional reduction*.
- Notice: percolation threshold p_c is a *decreasing* function of space-time dimension D

Monopole condensation

F. Gliozzi (DFT & INFN, Universitá di Torino

∃ > < ∃</p>

- t' Hooft and Mandelstam conjecture: The confining vacuum is a dual superconductor
- ⇒ There should be a "disorder" operator $\Phi(x)$ such that
 - it is not local in the gauge variables
 - $\langle \Phi \rangle = 0$ in deconfined vacuum
 - $\langle \Phi \rangle \neq 0$ in confined vacuum *monopole condensation*
- In standard percolation: two-point function $G(x, y) \equiv$ probability that the sites x and y are in the same cluster
 - G(x, y) cannot be rewritten in terms of Wilson loops: Connectivity (path between x and y) does not depend on linking properties (closed paths)
 - \Rightarrow $\lim_{x\to\infty} G(0,x) = 0$ iff $p < p_c$
 - \Rightarrow $\lim_{x\to\infty} G(0,x) \neq 0$ iff $p > p_c$
- \Rightarrow This strongly suggests $G(x, y) = \langle \Phi(x) \Phi(y) \rangle$

< ロ > < 同 > < 回 > < 回 >

$p < p_c$ Monopole mass
