## Roberto Casalbuoni

Department of Physics and INFN - Florence

## Insiscoclucijos

Motivations for the study of high-density QCD:

- Understanding the interior of CSO's
- Study of the QCD phase diagram at $\mathrm{T} \sim 0$ and high $\mu$

Asymptotic region in $\mu$ fairly well understood: existence of a CS phase. Real question: does this type of phase persists at relevant densities $\left(\sim 5-6 \rho_{0}\right)$ ?

## Stussissess

- Mini review of CFL and 2SC phases
- Pairing of fermions with different Fermi momenta
- The gapless phases g2SC and gCFL
- The LOFF phase and its phonons

## CJI cssjc $25 C^{\prime}$

Study of CS back to 1977 (Barrois 1977, Frautschi 1978, Bailin and Love 1984) based on Cooper instability:

At $T \sim 0$ a degenerate fermion gas is unstable

## Any weak attractive interaction leads to Cooper pair formation

$>$ Hard for electrons (Coulomb vs. phonons)
$>$ Easy in QCD for di-quark formation (attractive channel $\overline{3}$ )
$(3 \otimes 3=\overline{3} \oplus 6)$

# In QCD, CS easy for large $\mu$ due to asymptotic freedom 

At high $\mu, \mathrm{m}_{\mathrm{s}}, \mathrm{m}_{\mathrm{d}}, \mathrm{m}_{\mathrm{u}} \sim 0,3$ colors and 3 flavors
Possible pairings: $\langle 0| \psi_{i \mathrm{ia}}^{\alpha} \psi_{\mathrm{jb}}^{\beta}|0\rangle$

* Antisymmetry in color $(\alpha, \beta)$ for attraction
* Antisymmetry in spin (a,b) for better use of the Fermi surface
* Antisymmetry in flavor (i, j) for Pauli principle

# Only possible pairings 

## LL and RR

Favorite state CFL (color-flavor locking) (Alford, Rajagopal \& Wilczek 1999)
$\langle 0| \psi_{\mathrm{aL}}^{\alpha} \psi_{\mathrm{bL}}^{\beta}|0\rangle=-\langle 0| \psi_{\mathrm{aR}}^{\alpha} \psi_{\mathrm{bR}}^{\beta}|0\rangle=\Delta \varepsilon^{a \beta \mathrm{C}} \varepsilon_{\mathrm{abC}}$
Symmetry breaking pattern
$\mathrm{SU}(3)_{\mathrm{c}} \otimes \mathrm{SU}(3)_{\mathrm{L}} \otimes \mathrm{SU}(3)_{\mathrm{R}} \Rightarrow \mathrm{SU}(3)_{\mathrm{c}+\mathrm{L}+\mathrm{R}}$

## What happens going down with $\mu$ ? If $\mu \ll \mathrm{m}_{\mathrm{s}}$ we get

## 3 colors and 2 flavors (2SC)

$$
\langle 0| \psi_{\mathrm{aL}}^{\alpha} \psi_{\mathrm{bL}}^{\beta}|0\rangle=\Delta \varepsilon^{\alpha \beta 3} \varepsilon_{\mathrm{ab}}
$$

$\mathrm{SU}(3)_{\mathrm{c}} \otimes \mathrm{SU}(2)_{\mathrm{L}} \otimes \mathrm{SU}(2)_{\mathrm{R}} \Rightarrow \mathrm{SU}(2)_{\mathrm{c}} \otimes \mathrm{SU}(2)_{\mathrm{L}} \otimes \mathrm{SU}(2)_{\mathrm{R}}$

But what happens in real world ?

- $\mathrm{M}_{\mathrm{s}}$ not zero
(no free energy cost
- Neutrality with respect to em and color in neutral -> singlet, Amore et al. 2003)
- Weak equilibrium

> All these effects make Fermi momenta of different fermions unequal causing problems to the BCS pairing mechanism

Consider 2 fermions with $\mathrm{m}_{1}=\mathrm{M}, \mathrm{m}_{2}=0$ at the same chemical potential $\mu$. The Fermi momenta are

$$
\mathrm{p}_{\mathrm{F} 1}=\sqrt{\mu^{2}-\mathrm{M}^{2}}
$$

$$
\mathrm{p}_{\mathrm{F} 2}=\mu
$$

Effective chemical potential for the massive quark

Mismatch:

$$
\begin{aligned}
& \mu_{\mathrm{eff}}=\sqrt{\mu^{2}-\mathrm{M}^{2}} \approx \mu-\frac{\mathrm{M}^{2}}{2 \mu} \\
& \mathrm{tch}: \quad \delta \mu \approx \frac{\mathrm{M}^{2}}{2 \mu}
\end{aligned}
$$

If electrons are present, weak equilibrium makes chemical potentials of quarks of different charges unequal:

$$
d \rightarrow u e \bar{v} \quad \Rightarrow \quad \mu_{\mathrm{d}}-\mu_{\mathrm{u}}=\mu_{\mathrm{e}}
$$

In general we have the relation: $\quad\left(\mu_{\mathrm{i}}=\mu+\mathrm{Q} \mu_{\mathrm{Q}}\right)$

$$
\mu_{\mathrm{e}}=-\mu_{\mathrm{Q}}
$$

N.B. $\mu_{\mathrm{e}}$ is not a free parameter

Neutrality requires:

$$
\frac{\partial \mathrm{V}}{\partial \mu_{\mathrm{e}}}=-\mathrm{Q}=0
$$

Example 2SC: normal BCS pairing when

$$
\mu_{\mathrm{u}}=\mu_{\mathrm{d}} \Rightarrow \mathrm{n}_{\mathrm{u}}=\mathrm{n}_{\mathrm{d}}
$$

But neutral matter for
$\mathrm{n}_{\mathrm{d}} \approx 2 \mathrm{n}_{\mathrm{u}} \Rightarrow \mu_{\mathrm{d}} \approx 2^{1 / 3} \mu_{\mathrm{u}} \Rightarrow \mu_{\mathrm{e}}=\mu_{\mathrm{d}}-\mu_{\mathrm{u}} \approx \frac{1}{4} \mu_{\mathrm{u}} \neq 0$
Mismatch: $\quad \delta \mu=\frac{p_{\mathrm{F}}^{\mathrm{d}}-\mathrm{p}_{\mathrm{F}}^{\mathrm{u}}}{2}=\frac{\mu_{\mathrm{d}}-\mu_{\mathrm{u}}}{2}=\frac{\mu_{\mathrm{e}}}{2} \approx \frac{\mu_{\mathrm{u}}}{8} \neq 0$

Also color neutrality requires

$$
\frac{\partial \mathrm{V}}{\partial \mu_{3}}=\mathrm{T}_{3}=0, \quad \frac{\partial \mathrm{~V}}{\partial \mu_{8}}=\mathrm{T}_{8}=0
$$

As long as $\delta \mu$ is small no effects on BCS pairing, but when increased the BCS pairing is lost and two possibilities arise:

- The system goes back to the normal phase
- Other phases can be formed

In a simple model with two fermions at chemical potentials $\mu+\delta \mu, \mu-\delta \mu$ the system becomes normal at the Chandrasekhar-Clogston point. Another unstable phase exists.

The point $|\delta \mu|=\Delta$ is special. In the presence of a mismatch new features are present. The spectrum of quasiparticles is

$$
\mathrm{E}(\mathrm{p})=\left|\delta \mu \pm \sqrt{(\mathrm{p}-\mu)^{2}+\Delta^{2}}\right|
$$

For $|\delta \mu|<\Delta$, the gaps are $\Delta-\delta \mu$ and $\Delta+\delta \mu$
For $|\delta \mu|=\Delta$, an unpairing (blocking) region opens up and gapless modes are present.

$$
\mathrm{E}(\mathrm{p})=0 \Leftrightarrow \mathrm{p}=\mu \pm \sqrt{\delta \mu^{2}-\Delta^{2}}
$$

$2 \delta \mu \quad$ Energy cost for pairing
$2 \Delta \quad$ Energy gained in pairing

- 2 quarks ungapped $\mathrm{q}_{\mathrm{ub}}, \mathrm{q}_{\mathrm{db}}$
- 4 quarks gapped $q_{u r}, q_{u g}, q_{d r}, q_{d g}$

General strategy (NJL model):

- Write the free energy:

$$
\mathrm{V}\left(\mu, \mu_{3}, \mu_{8}, \mu_{\mathrm{e}}, \Delta\right)
$$

- Solve:
$\begin{array}{lll}\text { Neutrality } & \frac{\partial \mathrm{V}}{\partial \mu_{\mathrm{e}}}=\frac{\partial \mathrm{V}}{\partial \mu_{3}}=\frac{\partial \mathrm{V}}{\partial \mu_{8}}=0 \\ \text { Gap equation } & \frac{\partial \mathrm{V}}{\partial \Delta}=0\end{array}$
- For $|\delta \mu|>\Delta\left(\delta \mu=\mu_{\mathrm{e}} / 2\right) 2$ gapped quarks become gapless. The gapless quarks begin to unpair destroying the BCS solution. But a new stable phase exists, the gapless 2SC (g2SC) phase.
- It is the unstable phase which becomes stable in this case (and CFL, see later) when charge neutrality is required.

- But evaluation of the gluon masses (5 out of 8 become massive) shows an instability of the g2SC phase. Some of the gluon masses are imaginary (Huang and Shovkovy 2004).
- Possible solutions are: gluon condensation, or another phase takes place as a crystalline phase (see later), or this phase is unstable against possible mixed phases.
- Potential problem also in gCFL (calculation not yet done).

## Generalization to 3 flavors

$$
\langle 0| \psi_{\mathrm{aL}}^{\alpha} \psi_{\mathrm{bL}}^{\beta}|0\rangle=\Delta_{1} \varepsilon^{\alpha \beta 1} \varepsilon_{\mathrm{ab} 1}+\Delta_{2} \varepsilon^{\alpha \beta 2} \varepsilon_{\mathrm{ab} 2}+\Delta_{3} \varepsilon^{\alpha \beta 3} \varepsilon_{\mathrm{ab} 3}
$$

Different phases are characterized by different values for the gaps. For instance (but many other possibilities exist)

$$
\begin{array}{ll}
\mathrm{CFL}: & \Delta_{1}=\Delta_{2}=\Delta_{3}=\Delta \\
\mathrm{g} 2 \mathrm{SC}: & \Delta_{3} \neq 0, \Delta_{1}=\Delta_{2}=0 \\
\mathrm{gCFL}: & \Delta_{3}>\Delta_{2}>\Delta_{1}
\end{array}
$$

| $\begin{aligned} & \text { Gaps } \\ & \text { in } \\ & \text { gCFL } \end{aligned}$ | Q | 0 | 0 | 0 | -1 | +1 | -1 | +1 | 0 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | ru | gd | bs | rd | gu | rs | bu | gs | bd |
|  | ru |  | $\Delta_{3}$ | $\Delta_{2}$ |  |  |  |  |  |  |
|  | gd | $\Delta_{3}$ |  | $\Delta_{1}$ |  |  |  |  |  |  |
|  | bs | $\Delta_{2}$ | $\Delta_{1}$ |  |  |  |  |  |  |  |
|  | rd |  |  |  |  | $-\Delta_{3}$ |  |  |  |  |
|  | gu |  |  |  | $-\Delta_{3}$ |  |  |  |  |  |
|  | rs |  |  |  |  |  |  | $-\Delta_{2}$ |  |  |
|  | bu |  |  |  |  |  | $-\Delta_{2}$ |  |  |  |
|  | gs |  |  |  |  |  |  |  |  | - $\Delta$ |
|  | bd |  |  |  |  |  |  |  | $-\Delta_{1}$ |  |

Strange quark mass effects:

- Shift of the chemical potential for the strange quarks:

$$
\mu_{\mathrm{\alpha s}} \Rightarrow \mu_{\mathrm{\alpha s}}-\frac{\mathrm{M}_{\mathrm{s}}^{2}}{2 \mu}
$$

- Color and electric neutrality in CFL requires

$$
\mu_{8}=-\frac{\mathbf{M}_{\mathrm{s}}^{2}}{2 \mu}, \quad \mu_{3}=\mu_{\mathrm{e}}=0
$$

- gs-bd unpairing catalyzes CFL to gCFL

$$
\begin{gathered}
\delta \mu_{\mathrm{bd}-\mathrm{gs}}=\frac{1}{2}\left(\mu_{\mathrm{bd}}-\mu_{\mathrm{gs}}\right)=-\mu_{8}=\frac{\mathrm{M}_{\mathrm{s}}^{2}}{2 \mu} \\
\delta \mu_{\mathrm{rd}-\mathrm{gu}}=\mu_{\mathrm{e}}, \quad \delta \mu_{\mathrm{rs}-\mathrm{bu}}=\mu_{\mathrm{e}}-\frac{\mathrm{M}_{\mathrm{s}}^{2}}{2 \mu}
\end{gathered}
$$

It follows:
$\left.\left.\begin{array}{ll}\frac{\mathrm{M}^{2}}{\mu} & \text { Energy cost for pairing } \\ 2 \Delta & \text { Energy gained in pairing }\end{array}\right\} \xrightarrow{\frac{\mathrm{M}^{2}}{\mu}>2 \Delta} \begin{array}{l}\text { begins to unpair } \\ \hline\end{array}\right]$

Again, by using NJL model (modelled on one-gluon exchange):

- Write the free energy: $V\left(\mu_{,} \mu_{3}, \mu_{8}, \mu_{\mathrm{e}}, \mathrm{M}_{\mathrm{s}}, \Delta_{\mathrm{i}}\right)$
- Solve:

Neutrality $\quad \frac{\partial \mathrm{V}}{\partial \mu_{e}}=\frac{\partial \mathrm{V}}{\partial \mu_{3}}=\frac{\partial \mathrm{V}}{\partial \mu_{8}}=0$
Gap equations $\frac{\partial V}{\partial \Delta_{i}}=0$

- CFL $\mapsto$ gCFL $2^{\text {nd }} \operatorname{order}^{\circ}$ transition at $\mathrm{M}_{\mathrm{s}}{ }^{2} / \mu \sim 2 \Delta$, when the pairing gs-bd starts breaking
- gCFL has gapless quasiparticles. Interesting
 transport properties

- gCFL has $\mu_{\mathrm{e}}$ not zero, with charge cancelled by unpaired u quarks

- LOFF (Larkin, Ovchinnikov, Fulde \& Ferrel, 1964): ferromagnetic alloy with paramagnetic impurities.
- The impurities produce a constant exchange field acting upon the electron spins giving rise to an effective difference in the chemical potentials of the opposite spins producing a mismatch of the Fermi momenta

According to LOFF, close to first order point (CC point), possible condensation with non zero total momentum

$$
\overrightarrow{\mathrm{p}}_{1}=\overrightarrow{\mathrm{k}}+\overrightarrow{\mathrm{q}} \quad \overrightarrow{\mathrm{p}}_{2}=-\overrightarrow{\mathrm{k}}+\overrightarrow{\mathrm{q}} \quad \rightarrow\langle\psi(\mathrm{x}) \psi(\mathrm{x})\rangle=\Delta \mathrm{e}^{2 \mathrm{i} \cdot \overrightarrow{\mathrm{x}}}
$$

More generally $\longrightarrow\langle\psi(\mathrm{x}) \psi(\mathrm{x})\rangle=\sum_{\mathrm{m}} \Delta_{\mathrm{m}} \mathrm{c}_{\mathrm{m}} \mathrm{e}^{2 \mathrm{i} \overrightarrow{\mathrm{q}}_{\mathrm{m}} \cdot \overrightarrow{\mathrm{x}}}$

$$
\overrightarrow{\mathrm{p}}_{1}+\overrightarrow{\mathrm{p}}_{2}=2 \overrightarrow{\mathrm{q}}
$$

$|\overrightarrow{\mathrm{q}}| \quad$ fixed variationally

$$
\overrightarrow{\mathrm{q}} /|\overrightarrow{\mathrm{q}}| \begin{gathered}
\text { chosen } \\
\text { spontaneously }
\end{gathered}
$$

## Single plane wave:

$$
\begin{gathered}
\mathrm{E}(\overrightarrow{\mathrm{p}})-\mu \rightarrow \mathrm{E}( \pm \overrightarrow{\mathrm{p}}+\overrightarrow{\mathrm{q}})-\mu \mp \delta \mu \approx \sqrt{(\mathrm{p}-\mu)^{2}+\Delta^{2}} \mp \bar{\mu} \\
\bar{\mu}=\delta \mu-\overrightarrow{\mathrm{v}}_{\mathrm{F}} \cdot \overrightarrow{\mathrm{q}}
\end{gathered}
$$

Also in this case, for $\quad|\bar{\mu}|=\delta \mu-\vec{v}_{F} \cdot \overrightarrow{\mathrm{q}}<\Delta$ a unpairing (blocking) region opens up and gapless modes are present

Possibility of a crystalline structure (Larkin \&

> Ovchinnikov 1964, Bowers \& Rajagopal 2002)

$$
\langle\psi(\mathrm{x}) \psi(\mathrm{x})\rangle=\Delta \sum_{\left|\mathrm{q}_{\mathrm{i}}\right|=1.2 \delta \mu} \mathrm{e}^{2 \mathrm{i}_{\mathrm{i}} \cdot \overrightarrow{\mathrm{x}}}
$$

The $\mathrm{q}_{\mathrm{i}}$ 's define the crystal pointing at its vertices.

$$
P=2
$$

$P=4$

## Crystalline structures in LOFF

The LOFF phase is studied via a Ginzburg-Landau expansion of the grand potential

$$
\Omega=\alpha \Delta^{2}+\frac{\beta}{2} \Delta^{4}+\frac{\gamma}{3} \Delta^{6}+\cdots
$$

(for regular crystalline structures all the $\Delta_{\mathrm{q}}$ are equal)

The coefficients can be determined microscopically for the different structures (Bowers and Rajagopal (2002))

* Gap equation

* Propagator expansion

* Insert in the gap equation

We get the equation

$$
\alpha \Delta+\beta \Delta^{3}+\gamma \Delta^{5}+\cdots=0
$$

$\partial \Omega$

## $\partial \Delta$

# The first coefficient has universal structure, independent on the crystal. <br> $\beta \Delta^{3}=\underline{0}$ <br> From its analysis one draws the following results 

$$
\gamma \Delta^{5}=:!
$$

## $\delta \mu_{1}=\Delta_{\text {BCS }} / \sqrt{2}$

 $\delta \mu_{2} \approx 0.754 \Delta_{\mathrm{BCS}}$$$
\Omega_{\text {LofF }}-\Omega_{\text {normal }}=-0.44 \rho\left(\delta \mu-\delta \mu_{2}\right)^{2}
$$

$$
\Delta_{\mathrm{LOFF}} \approx 1.15 \sqrt{\left(\delta \mu_{2}-\delta \mu\right)}
$$

# Small window. Opens up in QCD?

Effective gap equation for the LOFF phase
(R.C., M. Ciminale, M. Mannarelli, G. Nardulli, M. Ruggieri \& R. Gatto, 2004)

For the single plane wave $(\mathrm{P}=1)$ the pairing region is defined by

$$
\begin{gathered}
\Delta_{\text {eff }}=\Delta \theta\left(\mathrm{E}_{\mathrm{u}}\right) \theta\left(\mathrm{E}_{\mathrm{d}}\right)= \begin{cases}\Delta & \text { for }\left(\mathrm{p}, \overrightarrow{\mathrm{v}}_{\mathrm{F}}\right) \in \mathrm{PR} \\
0 & \text { elsewhere }\end{cases} \\
\mathrm{E}_{\mathrm{u}, \mathrm{~d}}= \pm\left(\delta \mu-\overrightarrow{\mathrm{v}}_{\mathrm{F}} \cdot \overrightarrow{\mathrm{q}}\right)+\sqrt{\xi^{2}+\Delta^{2}}, \quad \xi=\mathrm{p}-\mu \\
\Delta=\frac{g \rho}{2} \int \frac{\mathrm{~d}}{\mathrm{v}} \int^{\delta} \int_{0}^{\delta} \mathrm{d} \xi \frac{\Delta_{\text {eff }}}{\sqrt{\xi^{2}+\Delta_{\text {eff }}^{2}}} \quad \rho=4 \frac{\mu^{2}}{\pi^{2}}
\end{gathered}
$$

How to obtain this result starting from an effective theory for fermions close to the Fermi surface? Problem:

$$
\mathfrak{L} \sim \Delta \mathrm{e}^{2 \mathrm{i} \cdot \overrightarrow{\mathrm{q}} \cdot \overrightarrow{\mathrm{r}}} \psi_{-\mathrm{v}}^{\mathrm{T}} \mathrm{C} \psi_{\mathrm{v}}
$$

where in the Fermi fields the large part in the momentum has been extracted

$$
\mathrm{p}=\mu \mathrm{v}_{\mathrm{F}}+\ell
$$

Solution: appropriate average procedure over the cell size

$$
\mathfrak{L} \rightarrow \Delta_{\mathrm{eff}} \psi_{-\mathrm{v}}^{\mathrm{T}} \mathrm{C} \psi_{\mathrm{v}}
$$

Average by

$$
\mathrm{g}_{\mathrm{R}}(\overrightarrow{\mathrm{r}})=\prod_{\mathrm{k}=1}^{3} \frac{\sin \left(\pi \mathrm{qr}_{\mathrm{k}} / \mathrm{R}\right)}{\pi \mathrm{r}_{\mathrm{k}}}
$$

When $\mathrm{R} / \pi \sim 1$ different from zero in a region of the order of the cell size. Condition satisfied if the gap is not too small.

For P plane waves

$$
\langle\psi(\mathrm{x}) \psi(\mathrm{x})\rangle=\Delta \sum_{\mathrm{k}=1}^{\mathrm{P}} \mathrm{e}^{2 \mathrm{i} \overrightarrow{\mathrm{a}}_{\mathrm{k}} \cdot \overrightarrow{\mathrm{x}}}
$$

an analogous average procedure gives pairing regions and effective gap given by

$$
\begin{aligned}
& \mathrm{P}_{\mathrm{k}}=\left\{\left(\mathrm{p}, \overrightarrow{\mathrm{v}}_{\mathrm{F}}\right) \mid \Delta_{\mathrm{E}}\left(\mathrm{p}, \overrightarrow{\mathrm{v}}_{\mathrm{F}}\right)=\mathrm{k} \Delta\right\} \\
& \Delta_{\mathrm{E}}\left(\mathrm{p}, \overrightarrow{\mathrm{v}}_{\mathrm{F}}\right)=\sum_{\mathrm{m}=1}^{\mathrm{P}} \Delta_{\text {eff }}\left(\mathrm{p}, \overrightarrow{\mathrm{v}}_{\mathrm{F}} \cdot \overrightarrow{\mathrm{q}}_{\mathrm{m}}\right)
\end{aligned}
$$

## We obtain the following gap equation

$$
\begin{aligned}
& \mathrm{P} \Delta=\frac{\mathrm{g} \rho}{2} \sum_{\mathrm{k}=1}^{\mathrm{P}} \iint_{\mathrm{P}_{\mathrm{k}}} \frac{\mathrm{~d} \overrightarrow{\mathrm{v}}}{4 \pi} \frac{\mathrm{~d} \xi}{2 \pi} \frac{\Delta_{\mathrm{E}}}{\sqrt{\xi^{2}+\Delta_{\mathrm{E}}^{2}}}= \\
&=\frac{\mathrm{g} \rho}{2} \sum_{\mathrm{k}=1}^{\mathrm{P}} \iint_{\mathrm{P}_{\mathrm{k}}} \frac{\mathrm{~d} \overrightarrow{\mathrm{v}}}{4 \pi} \frac{\mathrm{~d} \xi}{2 \pi} \frac{\mathrm{k} \Delta}{\sqrt{\xi^{2}+\mathrm{k}^{2} \Delta^{2}}}
\end{aligned}
$$

The result can be interpreted as having P quasi-particles each of one having a gap $\mathrm{k} \Delta, \mathrm{k}=1, \ldots, \mathrm{P}$.

The approximation is better far from a second order transition and it is exact for $\mathrm{P}=1$ (original FF case).

Evaluating the free energy at the CC point we see that the $\mathrm{P}=6$ case (octahedron) is favored. Then the cube takes over at $\delta \mu_{2} \sim 0.95 \Delta$

| $P$ | $z_{q}$ | $\frac{\Delta}{\Delta_{0}}$ | $\frac{2 \Omega}{p \Delta_{0}^{2}}$ |
| :---: | :---: | :---: | :---: |
| 1 | 0.78 | 0.24 | $-1.8 \times 10^{-3}$ |
| 2 | 1.0 | 0.75 | -0.08 |
| 6 | 0.9 | 0.28 | -0.11 |
| 8 | 0.9 | 0.21 | -0.09 |

| $P$ | $\delta \mu 2 / \Delta 0$ | Order | $z_{q}$ | $\Delta / \Delta 0$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 0.754 | II | 0.83 | 0 |
| 2 | 0.83 | I | 1.0 | 0.81 |
| 6 | 1.22 | I | 0.95 | 0.43 |
| 8 | 1.32 | I | 0.9 | 0.35 |

Two phase transitions from the CC point
$\left(\mathrm{M}_{\mathrm{s}}^{2} / \mu=4 \Delta_{2 \mathrm{SC}}\right)$ up to the cube case $\left(\mathrm{M}_{\mathrm{s}}{ }^{2} / \mu \sim 7.5 \Delta_{2 \mathrm{SC}}\right)$. Extrapolating to CFL ( $\Delta_{2 \mathrm{SC}} \sim 30 \mathrm{MeV}$ ) one gets that LOFF should be favored from about

| $P$ | $\delta \mu_{2} / \Delta_{0}$ | Order | $z_{q}$ | $\Delta / \Delta_{0}$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 0.754 | II | 0.83 | 0 |
| 2 | 0.83 | I | 1.0 | 0.81 |
| 6 | 1.22 | I | 0.95 | 0.43 |
| 8 | 1.32 | I | 0.9 | 0.35 |

$\mathrm{M}_{\mathrm{s}}^{2} / \mu \sim 120 \mathrm{MeV}$ up $\mathrm{M}_{\mathrm{s}}^{2} / \mu \sim 225 \mathrm{MeV}$

## Cosscjusjoss

- Under realistic conditions ( $\mathrm{M}_{\mathrm{s}}$ not zero, color and electric neutrality) new CS phases might exist
- In these phases gapless modes are present. This result might be important in relation to the transport properties inside a CSO.
