# QCD with non-zero baryon density

- Continuum:  $\mathcal{L} = \mathcal{L}_{QCD} + \mu J_0$ ,  $J_\mu = \bar{\psi} \gamma_\mu \psi$ ,  $\int d^3x J_0 = N_q - N_{\bar{q}}$

$$Z(\mu) = \text{Tr} \left( e^{-(H_{QCD} - \mu N)/T} \right)$$

- Lattice:  $\mu$  as the temporal component of a U(1) imaginary background field

$$U_4(n) \rightarrow e^{a\mu} U_4(n), \quad U_4^\dagger(n) \rightarrow e^{-a\mu} U_4^\dagger(n)$$

[F. Karsch, P. Hasenfratz, 1983]

$$\langle O \rangle = \frac{\int DU D\bar{\psi} D\psi O[U, \psi, \bar{\psi}] e^{-S_F[U, \psi, \bar{\psi}] - S_G[U]}}{\int DU D\bar{\psi} D\psi e^{-S_F[U, \psi, \bar{\psi}] - S_G[U]}}$$

$$S_F = \sum_{n,m} \bar{\psi}(n) M_{nm}[U, \mu] \psi(m) \longrightarrow \int D\bar{\psi} D\psi e^{-S_F[U, \psi, \bar{\psi}]} = \det M[U, \mu]$$

# The “sign” problem

$$\langle O \rangle = \frac{\int DU \langle O \rangle_{S_F} e^{-S_{\text{eff}}[U]}}{\int DU e^{-S_{\text{eff}}[U]}}, \quad \langle O \rangle_{S_F} = \frac{\int D\bar{\psi} D\psi O[U, \psi, \bar{\psi}] e^{-S_F[U, \psi, \bar{\psi}]}}{\int D\bar{\psi} D\psi e^{-S_F[U, \psi, \bar{\psi}]}}$$

$$S_{\text{eff}}[U] = S_G[U] - \ln \det M[U]$$

- In order to perform Monte Carlo simulations “det  $M$ ” must be **real**
  - **OK** for  $\mu = 0$  in SU(3), since  $M^\dagger = PMP^{-1}$ , with  $P = \gamma_5$  for Wilson,  $P = I$  for staggered fermions
  - **NO** for  $\mu \neq 0$  in SU(3), since  $M^\dagger(\mu) = M(-\mu)$
  - **OK** for finite isospin density; e.g., for  $N_f = 2$ ,  $(M(\mu)M(-\mu))^\dagger = M(\mu)M(-\mu)$
  - **OK** for  $\mu \neq 0$  in SU(2), owing to  $M^* = \tau_2 M \tau_2$
  - **OK** for  $\mu = i\mu_I$  in SU( $N_c$ ), being  $M^\dagger(i\mu) = M(i\mu)$

# The "sign" problem

$$\langle O \rangle = \frac{\int DU \langle O \rangle_{S_F} e^{-S_{\text{eff}}[U]}}{\int DU e^{-S_{\text{eff}}[U]}}, \quad \langle O \rangle_{S_F} = \frac{\int D\bar{\psi} D\psi O[U, \psi, \bar{\psi}] e^{-S_F[U, \psi, \bar{\psi}]}}{\int D\bar{\psi} D\psi e^{-S_F[U, \psi, \bar{\psi}]}}$$

$$S_{\text{eff}}[U] = S_G[U] - \ln \det M[U]$$

- In order to perform Monte Carlo simulations "det  $M$ " must be **real**
  - **OK** for  $\mu = 0$  in SU(3), since  $M^\dagger = PMP^{-1}$ , with  $P = \gamma_5$  for Wilson,  $P = I$  for staggered fermions
  - **NO** for  $\mu \neq 0$  in SU(3), since  $M^\dagger(\mu) = M(-\mu)$
  - **OK** for finite isospin density; e.g., for  $N_f = 2$ ,  
 $(M(\mu)M(-\mu))^\dagger = M(\mu)M(-\mu)$
  - **OK** for  $\mu \neq 0$  in SU(2), owing to  $M^* = \tau_2 M \tau_2$
  - **OK** for  $\mu = i\mu_I$  in SU( $N_c$ ), being  $M^\dagger(i\mu) = M(i\mu)$

# The “sign” problem

$$\langle O \rangle = \frac{\int DU \langle O \rangle_{S_F} e^{-S_{\text{eff}}[U]}}{\int DU e^{-S_{\text{eff}}[U]}}, \quad \langle O \rangle_{S_F} = \frac{\int D\bar{\psi} D\psi O[U, \psi, \bar{\psi}] e^{-S_F[U, \psi, \bar{\psi}]}}{\int D\bar{\psi} D\psi e^{-S_F[U, \psi, \bar{\psi}]}}$$

$$S_{\text{eff}}[U] = S_G[U] - \ln \det M[U]$$

- In order to perform Monte Carlo simulations “det  $M$ ” must be **real**
  - **OK** for  $\mu = 0$  in SU(3), since  $M^\dagger = PMP^{-1}$ , with  $P = \gamma_5$  for Wilson,  $P = I$  for staggered fermions

# Ways' out I

- to perform simulations at  $\mu=0$  and to take advantage of physical fluctuations in the thermal ensemble for extracting information at (small) non-zero  $\mu$ , after **reweighting**

$$\langle O \rangle_{\mu \neq 0} = \left\langle O \frac{\det(M(\mu))}{\det(M(0))} \right\rangle_{\mu=0} / \left\langle \frac{\det(M(\mu))}{\det(M(0))} \right\rangle_{\mu=0}$$

[I.M. Barbour et al., 1998]

**Multiparameter reweighting:** reweighting also in  $\beta$

[Z. Fodor, S.D. Katz, 2002 →]

- to **Taylor expand** in  $\mu$  the v.e.v. of interest and to calculate the coefficients of the expansion by numerical simulations at  $\mu = 0$

[S.A. Gottlieb, 1988] [QCD-TARO coll., 2001]

[C.R. Allton et al., 2002-2003-2005]

[R.V. Gavai, S. Gupta, 2003-2005] [S. Ejiri et al., 2006]

# Ways' out I

## Ways' out II

- to reorder the path integral representation of the partition function, by first calculating expectation values with constrained parameters and then weighting over the **density of states**

[G. Bhanot et al., 1987] [M. Karliner et al., 1988]

[A. Gocksch, 1988] [V. Azcoiti, G. Di Carlo, A.F. Grillo, 1990]

[X.-Q. Luo, 2001] [J. Ambjorn et al., 2002]

[Z. Fodor, S.D. Katz, C. Schmidt, 2005-2007]

- to consider the theory at **imaginary chemical potential**

$$U_4(n) \rightarrow e^{ia\mu_l} U_4(n), \quad U_4^\dagger(n) \rightarrow e^{-ia\mu_l} U_4^\dagger(n) = \left( e^{ia\mu_l} U_4(n) \right)^\dagger$$

for which  $\det M[U]$  is real and Monte Carlo simulations are feasible; this opens the way to two approaches...

## Ways' out II

- to reorder the path integral representation of the partition function, by first calculating expectation values with constrained parameters and then weighting over the **density of states**

[G. Bhanot et al., 1987] [M. Karliner et al., 1988]

[A. Gocksch, 1988] [V. Azcoiti, G. Di Carlo, A.F. Grillo, 1990]

$$U_4(n) \rightarrow e^{ia\mu_l} U_4(n), \quad U_4^\dagger(n) \rightarrow e^{-ia\mu_l} U_4^\dagger(n) = \left( e^{ia\mu_l} U_4(n) \right)^\dagger$$

for which  $\det M[U]$  is real and Monte Carlo simulations are feasible; this opens the way to two approaches...

## Ways' out III

- 1 to build the canonical partition function  $Z(n)$  by Fourier transform of the grand canonical function at imaginary chemical potential:

$$\begin{aligned}
 Z(n) &= \text{Tr} \left( e^{-H_{\text{QCD}}/T} \delta(N - n) \right) = \text{Tr} \left( e^{-H_{\text{QCD}}/T} \int_0^{2\pi} \frac{d\theta}{2\pi} e^{i\theta(N-n)} \right) \\
 &= \frac{1}{2\pi} \int_0^{2\pi} d\theta e^{-i\theta n} e^{-(H_{\text{QCD}} - i\theta TN)/T} \\
 &= \frac{1}{2\pi} \int_0^{2\pi} d\theta e^{-i\theta n} Z(\mu = i\theta T)
 \end{aligned}$$

[A. Hasenfratz, D. Toussaint, 1992]

[M.G. Alford, A. Kapustin, F. Wilczek, 1999]

[P. de Forcrand, S. Kratochvila, 2004-2005-2006]

[A. Alexandru et al., 2005]

# Ways' out IV

- 2 **Method of analytic continuation:** to perform numerical simulations at *imaginary* chemical potential and to analytically continue the results to real  $\mu$

[M.P. Lombardo, 2000] [A. Hart, M. Laine, O. Philipsen, 2001]

[Ph. de Forcrand, O. Philipsen, 2002-2003-2004]

[H.-S. Chen, X.-Q. Luo, 2005] [S. Kim et al., 2005]

[M.P. Lombardo, 2005] [M. D'Elia, F. Di Renzo, M.P. Lombardo, 2005]

[P. Cea, L. Cosmai, M. D'Elia, A.P., 2006 →]

[F. Karbstein, M. Thies, 2006]

[L.-K. Wu, X.-Q. Luo, H.-S. Chen, 2007]

# Ways' out V

- coupling  $\beta$  and chemical potential  $\mu$  can be varied independently
- no limitation from increasing lattice sizes
- extent of the attainable domain with real  $\mu$  is limited
  - 1 by the periodicity and non-analyticities for imaginary  $\mu$
  - 2 by the accuracy of the interpolation of data for imaginary  $\mu$

All the mentioned methods have roughly the same range of applicability ( $\mu/T \lesssim 1$ ), although with different systematics, and agree inside this range

[O. Philipsen, Lattice 2005]

[C. Schmidt, Lattice 2006]

# QCD with imaginary chemical potential

- $SU(N_c)$  gauge theory with imaginary  $\mu$

$$\mu \rightarrow i\nu, \quad Z(\theta) = \text{Tr} \left[ e^{-\beta H + i\theta \hat{N}} \right], \quad \theta = \beta\nu, \quad \beta = \frac{1}{T}$$

- Free quarks ( $N = 0, 1, 2, \dots$ )  $\rightarrow Z(\theta)$  periodic with  $2\pi$
- Color singlets ( $N$  multiple of  $N_c$ )  $\rightarrow Z(\theta)$  periodic with  $2\pi/N_c$
- [A. Roberge, N. Weiss, 1986] have shown that
  - $Z(\theta)$  is **always** periodic with  $2\pi/N_c$
  - $F(\theta) = -\ln Z(\theta)/\beta$ 
    - $T < T_E$ : regular function of  $\theta$  (tool: hopping parameter expansion)
    - $T > T_E$ : discontinuous function in  $\theta = 2\pi(k + 1/2)/N_c$  (tool: perturbative evaluation of the effective potential for the Wilson line)
- This scenario has been confirmed in numerical simulations in  $SU(3)$  [Ph. de Forcrand, O. Philipsen, 2002; M. D'Elia, M.P. Lombardo, 2003] and in  $SU(2)$  [P. Giudice, A.P., 2004]

# QCD with imaginary chemical potential

# Outline

- 1 Introduction
  - QCD phase diagram
  - QCD with non-zero baryon density
  - The “sign” problem
  - Ways out
- 2 The method of analytic continuation
  - QCD with imaginary chemical potential
  - **Description of the method**
  - Numerical test
- 3 Conclusions

# Description of the method

- Strategy of the method of analytic continuation

- determine  $\langle \mathcal{O} \rangle$  for a set of value of imaginary chemical potential,  
 $\mu = i\mu_I$
- interpolate  $\langle \mathcal{O} \rangle(\mu)$  with a polynomial:

$$\langle \mathcal{O} \rangle(\mu) = a_0 + a_2\mu^2 + a_4\mu^4 + a_6\mu^6 + O(\mu^8)$$

- analytically continue to  $\mu = \mu_R$  by the replacement  $\mu^2 \rightarrow -\mu^2$

$$\langle \mathcal{O} \rangle(\mu) = a_0 - a_2\mu^2 + a_4\mu^4 - a_6\mu^6 + O(\mu^8)$$

- Applied in

- SU(3),  $n_f = 2$  [Ph. de Forcrand, O. Philipsen, 2002]
- SU(3),  $n_f = 2$  (Wilson) [L.-K. Wu, X.-Q. Luo, H.-S. Chen, 2007]
- SU(3),  $n_f = 3$  [Ph. de Forcrand, O. Philipsen, 2003]
- SU(3),  $n_f = 4$   
 [M. D'Elia, M.P. Lombardo, 2003; V. Azcoiti et al., 2004-2005]
- SU(3),  $n_f = 4$  (Wilson) [H.-S. Chen, X.-Q. Luo, 2005]

# Description of the method

- Tested in
  - strong-coupling QCD [M.P. Lombardo, 2000]
  - 3d SU(3) + adjoint Higgs model [A. Hart, M. Laine, O. Philipsen, 2001]
  - SU(2),  $n_f = 8$  [P. Giudice, A.P., 2004; P. Cea, L. Cosmai, M. D'Elia, A.P., 2006]
  - 3d 3-state Potts model [S. Kim et al., 2005]
  - 2d Gross-Neveu at large  $N$  [F. Karbstein, M. Thies, 2006]
- In most cases a polynomial has been used as interpolating function, sometimes a Fourier sum for the low-temperature regime [M. D'Elia, M.P. Lombardo, 2002];
- A careful numerical analysis in SU(2) has shown that a considerable improvement can be achieved at high temperatures if ratio of polynomials [M.P. Lombardo, Lattice 2005] are used instead [P. Cea, L. Cosmai, M. D'Elia, A.P., 2006; A.P., SM&FT 2006]

# Analytic continuation of the critical line

- The method of analytic continuation is extensively applied to the critical line itself.

# Analytic continuation of the critical line: strategy

## Strategy

- locate the (pseudo-)critical  $\beta$ 's for several fixed values of the **imaginary** chemical potential, by looking for peaks in the susceptibilities of a given observable
- interpolate the critical  $\beta$ 's obtained at **imaginary chemical potential** with an analytic function of  $\mu$ , to be then extrapolated to real chemical potential
- **if the theory is free from the sign problem**, compare the extrapolated curve with the determinations of the critical  $\beta$ 's at **real** chemical potential.

Observables: chiral condensate, Polyakov loop, plaquette.

# Outline

- 1 Introduction
  - QCD phase diagram
  - QCD with non-zero baryon density
  - The “sign” problem
  - Ways out
- 2 The method of analytic continuation
  - QCD with imaginary chemical potential
  - Description of the method
  - Numerical test
- 3 Conclusions

# Numerical test

The test is performed in two theories free from the sign problem:

- SU(2) with  $n_f=8$  staggered fermions
  - $16^3 \times 4$  lattice, fermion mass  $am=0.07$  and  $am=0.2$
  - $16^3 \times 6$  lattice, fermion mass  $am=0.07$
- SU(3) with finite isospin density,  $n_f=8$  staggered fermions,  $8^3 \times 4$  lattice, fermion mass  $am=0.1$

Technical details:

- hybrid Monte Carlo algorithm, with  $dt=0.01$  (*exact*  $\phi$  algorithm [S.A. Gottlieb et al., 1987]).
- statistics 10k  $\div$  20k
- simulations performed mostly on the computer facilities at the **INFN APEnext Computing Center**

# Conclusions

- We have tested the **analytic continuation of the critical line** in the  $(T, \mu)$ -plane from imaginary to real chemical potential in 2-color QCD and, preliminarily, in SU(3) with finite isospin density.
- We have found that the critical line around  $\mu = 0$  can be described by an **analytic function**.
- However, when trying to infer the behavior of the critical line at real  $\mu$  from the extrapolation of its behavior at imaginary  $\mu$ , a very large precision is needed to get the correct result.
- In the case of polynomial interpolations, there is a clear indication that terms of order  $\mu^4$  or even  $\mu^6$  play a relevant role at  $\mu^2 > 0$ , but are less visible at  $\mu^2 < 0$ , this calling for an accurate knowledge of the critical line in all the first RW sector.
- We have preliminary indications that in 2-color QCD this effect is strongly dependent on the fermionic mass and is more pronounced toward the chiral limit; in SU(3) with finite isospin density it seems to be less severe, but further investigations are needed.

# Conclusions

# Roberge-Weiss' proof I

$$Z(\theta) = \int D\psi D\bar{\psi} DA_\mu \exp \left\{ - \int d^4x \left[ \bar{\psi}(\gamma D - m)\psi - \frac{1}{4}F^2 - i\frac{\theta}{\beta}\psi^\dagger\psi \right] \right\}$$

time interval running from  $\tau = 0$  to  $\tau = \beta$   
 periodic b.c. for  $A$ , anti-periodic b.c. for  $\psi$

- change of variables I

$$\psi(x, \tau) \longrightarrow \exp(i\tau\theta/\beta) \psi(x, \tau)$$

$$Z(\theta) = \int D\psi D\bar{\psi} DA_\mu \exp \left\{ - \int d^4x \left[ \bar{\psi}(\gamma D - m)\psi - \frac{1}{4}F^2 \right] \right\}$$

with  $\psi(x, \beta) = -\exp(i\theta)\psi(x, 0)$

# Roberge-Weiss' proof II

- change of variables II

$$\psi \longrightarrow U\psi, \quad A \longrightarrow UAU^{-1} - \frac{i}{g}(\partial U)U^{-1}$$

$U(x, \tau) \in \text{SU}(N_c)$ ,  $U(x, \beta) = \exp(2\pi ik/N_c) U(x, 0)$ ,  $k$  integer  
 i.e.  $U$  periodic up to an element of  $\mathbf{Z}(N_c)$

$$Z(\theta) = \int D\psi D\bar{\psi} DA_\mu \exp \left\{ - \int d^4x \left[ \bar{\psi}(\gamma D - m)\psi - \frac{1}{4}F^2 \right] \right\}$$

with  $\psi(x, \beta) = -\exp(2\pi ik/N_c) \exp(i\theta)\psi(x, 0)$

i.e.  $Z(\theta) = Z(\theta + 2\pi k/N_c)$

## Roberge-Weiss' proof III

- V.e.v.'s of observables which are not modified by the above changes of variables (e.g. chiral condensate, fermionic number density) have the same periodicity of the partition function,  $2\pi/N_c$
- The v.e.v. of the Polyakov loop is  $2\pi/N_c$  periodic up to an element of  $Z(N_c)$ :

$$\langle L \rangle_{\theta+2\pi k/N_c} = \exp(2\pi i k / N_c) \langle L \rangle_{\theta}$$

$$k = 0, 1, \dots, N_c - 1$$

so, in fact, the periodicity is  $2\pi$
